

What is ADHD?

Information for parents

© Shutterstock.com/miodinka

Attention Deficit Hyperactivity Disorder (ADHD) is a neurodevelopmental disorder and is defined by NICE as a pattern of inattention, impulsivity and/ or hyperactivity that is persistent and interferes with functioning or development. Symptoms will:

- start before age 12
- occur in more than one setting
- be present for at least 6 months
- significantly impact on social and academic performance
- not be linked to another mental disorder/ diagnosis

Inattention

You may observe your child experiencing difficulty:

- Remaining on task, does not pay close attention to detail
- Being easily distracted/ loses focus, doesn't appear to listen when spoken to
- Being disorganised, losing or forgetting things
- Avoids activities that need sustained concentration/ mental effort.

Hyperactivity

You may observe your child to be:

- Excessively active
- Unable to sit still, fidgeting or squirming in their seat
- Getting up in class and walking around when remaining seated is expected
- Running or climbing more than other children
- Talking excessively, making noises or tapping, inability to play quietly.

Impulsivity

Your child may:

- Have limited awareness of danger, they may do things that put them at risk such as running out in to the road without looking
- Not think about the consequences of their actions, they may say or do something that gets them in to trouble or puts them in danger
- Shout out (rather than put their hand up), talk over or interrupt others
- Start arguments or fights
- Teenagers may engage in risky activities such as drinking alcohol, smoking cannabis or having underage/ unprotected sex.

What causes ADHD?

- Certain areas of the brain (including the frontal lobe, basal ganglia and cerebellum) play a significant role in ADHD as these areas of the brain are involved in complex processes that regulate behaviour. These processes are called executive functions and include regulation

of inhibition, working memory, planning, self-monitoring, verbal regulation, motor control and emotional regulation. According to the National Institute for Mental Health the brain matures in a normal pattern in children with ADHD, however there is a delay of 2 to 3 years compared with other children their age without ADHD

- Fewer chemicals (noradrenaline and dopamine) in the nerve endings of the frontal lobe of the brain to carry messages to other parts of the brain and around the body
- Exposure of the foetus during pregnancy to toxic substances such as alcohol, tobacco or illicit substances
- Heredity – ADHD can be passed on genetically, more than one generation of the same family can have a diagnosis
- Low birth weight
- Being born prematurely (before 37 weeks gestation)
- Brain trauma – in the womb or during the first few years of life

What does NOT cause ADHD?

- Diet – it was previously believed that ADHD could be caused by allergies or sensitivities to food, however research carried out over 20 years has not supported this belief.
- Social, cultural or environmental factors – ADHD does not discriminate and affects children from all backgrounds

ADHD facts and figures:

- Approximately 2.4% of the child population has a diagnosis of ADHD
- ADHD is more commonly diagnosed in boys than girls, ratio is approximately 4:1
- Approximately 15% of children retain their diagnosis of ADHD in to adulthood. There appears to be a lack of research and this is the result from only one study so is by no means conclusive

ADHD and other difficulties

It is not unusual for children and young people with ADHD to have other difficulties and your child may already have other diagnoses.

There are also other things such as attachment difficulties or severe lack of sleep that can present as similar to ADHD. Other potential reasons for your child's symptoms are considered during the assessment for ADHD and prior to diagnosis.
